

Vehicle component *testing*

Testing of Interior/Exterior Components

ISO TS 16949, which is commonly used in the automotive industry, recommends that „DIN EN ISO 17025“ accredited testing laboratories be commissioned for analyses. This condition is met by our laboratories. Especially for automotive suppliers in the fields of plastic construction, coating protection systems, electronic components, battery, engine, and transmission components, we carry out tests according to automotive standards.

Testing of material properties

Do the plastics and metals required to produce a component fulfill the necessary properties to meet the automotive industry specification?

Our material experts check the quality of your products and compliance with normative requirements - from hardness to flexural strength, from tensile testing to impact strength, from burning behavior to media resistance.

Emission and odor behavior of components

With new user interfaces, new materials, and corresponding customization options, the importance of material quality and processing in the vehicle interior is increasing. The emission of volatile organic compounds (VOC) and the proportion of condensable substances (FOG) from vehicle interior parts are therefore of corresponding importance. They influence the quality of indoor air in vehicles and are relevant for health and driving comfort.

Using test chamber measurements, odor measurements, and pollutant analyses, automotive interior parts can be tested accordingly and the emission behavior evaluated. The DEKRA test laboratory offers comprehensive measurement and analysis procedures for test chamber measurements, VOC screenings, and single substance analysis.

Environmental simulation and corrosion testing

How resistant are products to thermal and climatic loads? How quickly does the chrome surface of a radiator grille corrode in salt spray? How do chrome-plated plastic door handles change during continuous use in different climates?

During their service life, parts, assemblies, or technical products are exposed to various environmental influences and must function perfectly. Environmental influences include any form of chemical, physical, or other environmental impact on the product. We simulate these climatic conditions in advance and use different stress tests to check whether the function of the products is affected.

Surface testing

We carry out surface tests both to characterize surfaces and their properties and to check the protective function of the surface coating (for example, corrosion protection, UV/light protection, mechanical stress, media resistance, coating thickness). For the characterization of surfaces, their coatings, and properties, for the determination of surface defects and surface durability, we offer selected tests according to OEM specifications.

Damage investigations in case of field failures according to VDI directive 3822

As a central laboratory service at DEKRA, we offer you interdisciplinary materials expertise to carry out root cause analysis in the event of complaints about component parts. Microscopic fracture testing with complementary testing capabilities around product property, manufacturing process, and

material specification, combined with our materials knowhow, are our services for successful complaint processing. We help you to implement the findings from the damage analysis on your component in production!

DEKRA's range of services for testing specific requirements in the automotive industry

Material testing according to OEM requirement	Component testing according to OEM requirement	Assembly testing according to OEM requirement
